#### Lecture #35

Public Service Announcement. "Hackers@Berkeley is hosting BEARHACK this Saturday at 11AM in the Wozniak Lounge. It's a 24 hour hackathon - there'll be tons of good food (Cheeseboard, sushi & boba!), activities (including massages!), and prizes (including an Occulus Rift).

• Today: Dynamic programming and memoization.

# Dynamic Programming

- A puzzle (D. Garcia):
  - Start with a list with an even number of non-negative integers.
  - Each player in turn takes either the leftmost number or the rightmost.
  - Idea is to get the largest possible sum.
- Example: starting with (6, 12, 0, 8), you (as first player) should take the 8. Whatever the second player takes, you also get the 12, for a total of 20.
- Assuming your opponent plays perfectly (i.e., to get as much as possible), how can you maximize your sum?
- Can solve this with exhaustive game-tree search.

### Obvious Program

Recursion makes it easy, again:

```
int bestSum (int[] V) {
  int total, i, N = V.length;
  for (i = 0, total = 0; i < N; i += 1) total += V[i];
  return bestSum (V, 0, N-1, total);
}
/** The largest sum obtainable by the first player in the choosing
 * game on the list V[LEFT .. RIGHT], assuming that TOTAL is the
 * sum of all the elements in V[LEFT .. RIGHT]. */
int bestSum (int[] V, int left, int right, int total) {
  if (left > right)
   return 0;
  else {
    int L = total - bestSum (V, left+1, right, total-V[left]);
    int R = total - bestSum (V, left, right-1, total-V[right]);
    return Math.max (L, R);
}
}
```

ullet Time cost is  $C(0)=1,\ C(N)=2C(N-1)$ ; so  $C(N)\in\Theta(2^N)$ 

#### Still Another Idea from CS61A

- The problem is that we are recomputing intermediate results many times.
- Solution: memoize the intermediate results. Here, we pass in an  $N \times N$  array (N = V.length) of memoized results, initialized to -1.

```
int bestSum (int[] V, int left, int right, int total, int[][] memo) {
  if (left > right)
    return 0;
  else if (memo[left][right] == -1) {
    int L = total - bestSum (V, left+1, right, total-V[left], memo);
    int R = total - bestSum (V, left, right-1, total-V[right], memo);
    memo[left][right] = Math.max (L, R);
  }
  return memo[left][right];
}
```

ullet Now the number of recursive calls to bestSum must be  $O(N^2)$ , for N= the length of V, an enormous improvement from  $\Theta(2^N)!$ 

#### Iterative Version

• I prefer the recursive version, but the usual presentation of this idea—known as dynamic programming—is iterative:

```
int bestSum (int[] V) {
  int[][] memo = new int[V.length][V.length];
  int[][] total = new int[V.length][V.length];
  for (int i = 0; i < V.length; i += 1)
    memo[i][i] = total[i][i] = V[i];
  for (int k = 1; k < V.length; k += 1)
    for (int i = 0; i < V.length-k-1; i += 1) {
      total[i][i+k] = V[i] + total[i+1][i+k];
      int L = total[i][i+k] - memo[i+1][i+k];
      int R = total[i][i+k] - memo[i][i+k-1];
      memo[i][i+k] = Math.max (L, R);
    }
  return memo[0][V.length-1];
}</pre>
```

- That is, we figure out ahead of time the order in which the memoized version will fill in memo, and write an explicit loop.
- Save the time needed to check whether result exists.
- But I say, why bother?

## Longest Common Subsequence

- Problem: Find length of the longest string that is a subsequence of each of two other strings.
- Example: Longest common subsequence of "sally\_sells\_sea\_shells\_by\_the\_seashore" and  $"sarah_{\sqcup}sold_{\sqcup}salt_{\sqcup}sellers_{\sqcup}at_{\sqcup}the_{\sqcup}salt_{\sqcup}mines"$ is "sauslusausellsuutheusae" (length 23)
- Similarity testing, for example.
- Obvious recursive algorithm:

```
/** Length of longest common subsequence of SO[0..k0-1]
   and S1[0..k1-1] (pseudo Java) */
static int lls (String SO, int kO, String S1, int k1) {
  if (k0 == 0 \mid \mid k1 == 0) return 0;
  if (S0[k0-1] == S1[k1-1]) return 1 + lls (S0, k0-1, S1, k1-1);
 else return Math.max (lls (S0, k0-1, S1, k1), lls (S0, k0, S1, k1-1);
}
```

Exponential, but obviously memoizable.

## Memoized Longest Common Subsequence

```
/** Length of longest common subsequence of SO[0..k0-1]
 * and S1[0..k1-1] (pseudo Java) */
static int lls (String SO, int kO, String S1, int k1) {
  int[][] memo = new int[k0+1][k1+1];
  for (int[] row : memo) Arrays.fill (row, -1);
  return lls (S0, k0, S1, k1, memo);
private static int lls (String SO, int kO, String S1, int k1, int[][] memo) {
  if (k0 == 0 \mid \mid k1 == 0) return 0;
  if (memo[k0][k1] == -1) {
    if (S0[k0-1] == S1[k1-1])
      memo[k0][k1] = 1 + lls (S0, k0-1, S1, k1-1, memo);
    else
      memo[k0][k1] = Math.max (lls (S0, k0-1, S1, k1, memo),
                                lls (S0, k0, S1, k1-1, memo));
  }
  return memo[k0][k1];
```

#### Q: How fast will the memoized version be?

## Memoized Longest Common Subsequence

```
/** Length of longest common subsequence of SO[0..k0-1]
 * and S1[0..k1-1] (pseudo Java) */
static int lls (String SO, int kO, String S1, int k1) {
  int[][] memo = new int[k0+1][k1+1];
  for (int[] row : memo) Arrays.fill (row, -1);
  return lls (S0, k0, S1, k1, memo);
private static int lls (String SO, int kO, String S1, int k1, int[][] memo) {
  if (k0 == 0 \mid \mid k1 == 0) return 0;
  if (memo[k0][k1] == -1) {
    if (S0[k0-1] == S1[k1-1])
      memo[k0][k1] = 1 + lls (S0, k0-1, S1, k1-1, memo);
    else
      memo[k0][k1] = Math.max (lls (S0, k0-1, S1, k1, memo),
                                lls (S0, k0, S1, k1-1, memo));
  }
  return memo[k0][k1];
```

#### Q: How fast will the memoized version be? $\Theta(k_0 \cdot k_1)$
