CS61B Lecture #32

Today:

- Pseudo-random Numbers (Chapter 11)
- What use are random sequences?
- What are "random sequences"?
- Pseudo-random sequences.
- How to get one.
- Relevant Java library classes and methods.
- Random permutations.

What Is a "Random Sequence"?

- How about: "a sequence where all numbers occur with equal frequency"?
 - Like 1, 2, 3, 4, ...?
- Well then, how about: "an unpredictable sequence where all numbers occur with equal frequency?"
 - Like 0, 0, 0, 1, 1, 2, 2, 2, 2, 2, 3, 4, 4, 0, 1, 1, 1,...?
- Besides, what is wrong with 0, 0, 0, 0, ... anyway? Can't that occur by random selection?

Why Random Sequences?

- Choose statistical samples
- Simulations
- Random algorithms
- Cryptography:
 - Choosing random keys
 - Generating streams of random bits (e.g., SSL xor's your data with a regeneratable, pseudo-random bit stream that only you and the recipient can generate).
- And, of course, games

Pseudo-Random Sequences

- Even if definable, a "truly" random sequence is difficult for a computer (or human) to produce.
- For most purposes, need only a sequence that satisfies certain statistical properties, even if deterministic.
- Sometimes (e.g., cryptography) need sequence that is hard or impractical to predict.
- Pseudo-random sequence: deterministic sequence that passes some given set of statistical tests.
- For example, look at lengths of runs: increasing or decreasing contiquous subsequences.
- Unfortunately, statistical criteria to be used are quite involved. For details, see Knuth.

Generating Pseudo-Random Sequences

- Not as easy as you might think.
- Seemingly complex jumbling methods can give rise to bad sequences.
- Linear congruential method is a simple method that has withstood test of time:

$$X_0 =$$
arbitrary seed
 $X_i = (aX_{i-1} + c) \bmod m, i > 0$

- \bullet Usually, m is large power of 2.
- ullet For best results, want $a\equiv 5 \bmod 8$, and a, c, m with no common factors.
- This gives generator with a period of m (length of sequence before repetition), and reasonable potency (measures certain dependencies among adjacent $X_{i\cdot}$)
- ullet Also want bits of a to "have no obvious pattern" and pass certain other tests (see Knuth).
- ullet Java uses $a=25214903917,\, c=11,\, m=2^{48},\, {
 m to}$ compute 48-bit pseudo-random numbers but I haven't checked to see how good this is.

Other Generators

Additive generator:

$$X_n = \begin{cases} \text{arbitary value}, & n < 55\\ (X_{n-24} + X_{n-55}) \bmod 2^e, & n \ge 55 \end{cases}$$

- Other choices than 24 and 55 possible.
- \bullet This one has period of $2^f(2^{55}-1)$, for some f < e.
- Simple implementation with circular buffer:

i = (i+1) % 55;

$$X[i] += X[(i+31) \% 55]$$
; // Why +31 (55-24) instead of -24? return $X[i]$: /* modulo 2^{32} */

• where X[0 .. 54] is initialized to some "random" initial seed values.

What Can Go Wrong?

- \bullet Short periods, many impossible values: E.g., a, c, m even.
- ullet Obvious patterns. E.g., just using lower 3 bits of X_i in Java's 48-bit generator, to get integers in range 0 to 7. By properties of modular arithmetic,

$$X_i \mod 8 = (25214903917X_{i-1} + 11 \mod 2^{48}) \mod 8$$

= $(5(X_{i-1} \mod 8) + 3) \mod 8$

so we have a period of 8 on this generator; sequences like

$$0, 1, 3, 7, 1, 2, 7, 1, 4, \dots$$

are impossible. This is why Java doesn't give you the raw 48 bits.

- Bad potency leads to bad correlations.
 - E.g. Take c=0, a=65539, $m=2^{31}$, and make 3D points: $(X_i/S,X_{i+1}/S,X_{i+2}/S)$, where S scales to a unit cube.
 - Points will be arranged in parallel planes with voids between.
 - So, "random points" won't ever get near many points in the cube.

Adjusting Range and Distribution

- ullet Given raw sequence of numbers, X_i , from above methods in range (e.g.) O to 2^{48} , how to get uniform random integers in range O to n-1?
- \bullet If $n=2^k$, is easy: use top k bits of next X_i (bottom k bits not as "random")
- ullet For other n, be careful of slight biases at the ends. For example, if we compute $X_i/(2^{48}/n)$ using all integer division, and if $(2^{48}/n)$ doesn't come out even, then you can get n as a result (which you don't want).
- Easy enough to fix with floating point, but can also do with integers; one method (used by Java for type int):

```
/** Random integer in the range 0 .. n-1, n>0. */ int nextInt (int n) { long X = next random long (0 \le X < 2^{48}); if (n is 2^k for some k) return top k bits of X; int MAX = largest multiple of n that is < 2^{48}; while (X_i >= MAX) X = next random long (0 \le X < 2^{48}); return X_i / (MAX/n); }
```

Arbitrary Bounds

- \bullet How to get arbitrary range of integers (L to U)?
- To get random float, x in range $0 \le x < d$, compute return d*nextInt (1<<24) / (1<<24);
- Random double a bit more complicated: need two integers to get enough bits.

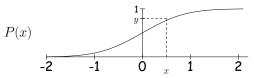

```
long bigRand = ((long) nextInt(1<<26) << 27) + (long) nextInt(1<<27);
return d * bigRand / (1L << 53);</pre>
```

Other Distributions

• Can also turn uniform random integers into arbitrary other distributions, like the Gaussian.

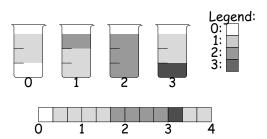

- ullet Curve is the desired probability distribution (P(x) is the probability that a certain random variable is $\leq x$.)
- ullet Choose y uniformly between 0 and 1, and the corresponding x will be distributed according to P.

CS61B: Lecture #32 10

Computing Arbitrary Discrete Distribution

• Example from book: want integer values X_i with $\Pr(X_i = 0) = 1/12$, $\Pr(X_i = 1) = 1/2$, $\Pr(X_i = 2) = 1/3$, $\Pr(X_i = 3) = 1/12$:

- ullet To get desired probabilities, choose floating-point number, $0 \le R_i < 4$, and see what color you land on.
- $\bullet \le 2$ colors in each beaker $\equiv \le 2$ colors between i and i+1.

```
return (R_i \% 1.0 > v[(int) R_i]) where

? top[(int) R_i] v = \{ 1.0/3.0, 2.0/3.0, 0, 1.0/3.0 \};

: bot[R_i]; top = \{ 1, 2, 2, 1 \},

bot = \{ 0, 1, /* ANY */ 0, 3 \};
```

Java Classes

- Math.random(): random double in [0..1).
- Class java.util.Random: a random number generator with constructors:

Random() generator with "random" seed (based on time).

Random(seed) generator with given starting value (reproducible).

Methods

next(k) k-bit random integer

nextInt(n**)** int in range [0..n).

nextLong() random 64-bit integer.

nextBoolean(), nextFloat(), nextDouble() Next random values of other
primitive types.

nextGaussian() normal distribution with mean 0 and standard deviation 1 ("bell curve").

ullet Collections.shuffle(L,R) for list R and Random R permutes L randomly (using R).

Shuffling

- A shuffle is a random permutation of some sequence.
- ullet Obvious dumb technique for sorting N-element list:
 - Generate N random numbers
 - Attach each to one of the list elements
 - Sort the list using random numbers as keys.
- Can do quite a bit better:

```
void shuffle (List L, Random R) {
  for (int i = L.size (); i > 0; i -= 1)
     swap element i-1 of L with element R.nextInt (i) of L;
}
```

• Example:

Alternative Selection Algorithm (Floyd)

```
/** Random sequence of K distinct integers
* from 0..N-1, 0<=K<=N. */
IntList selectInts(int N, int K, Random R)
 IntList S = new IntList();
 for (int i = N-K; i < N; i += 1) {
   // All values in S are < i
    int s = R.randInt(i+1); // 0 <= s <= i < N
    if (s == S.get(j) \text{ for some } j)
     // Insert value i (which can't be there
     // yet) after the s (i.e., at a random
     // place other than the front)
     S.add (j+1, i);
    else
      // Insert random value s at front
      S.add (0, s);
 return S;
```

Example

```
i s S

5 4 [4]

6 2 [2,4]

7 5 [5,2,4]

8 5 [5,8,2,4]

9 4 [5,8,2,4,9]

selectRandomIntegers (10, 5, R)
```

Random Selection

ullet Same technique would allow us to select N items from list:

```
/** Permute L and return sublist of K>=0 randomly
 * chosen elements of L, using R as random source. */
List select (List L, int k, Random R) {
  for (int i = L.size (); i+k > L.size (); i -= 1)
    swap element i-1 of L with element
    R.nextInt (i) of L;
  return L.sublist (L.size ()-k, L.size ());
}
```

• Not terribly efficient for selecting random sequence of K distinct integers from [0..N), with $K \ll N$.
